

ABSTRACT

A method and apparatus for the manipulation of colloidal particles and
5 biomolecules at the interface between an insulating electrode such as silicon oxide and an
electrolyte solution. Light-controlled electrokinetic assembly of particles near surfaces relies
on the combination of three functional elements: the AC electric field-induced assembly of
planar aggregates; the patterning of the electrolyte/silicon oxide/silicon interface to exert
spatial control over the assembly process; and the real-time control of the assembly process
10 via external illumination. The present invention provides a set of fundamental operations
enabling interactive control over the creation and placement of planar arrays of several types
of particles and biomolecules and the manipulation of array shape and size. The present
invention enables sample preparation and handling for diagnostic assays and biochemical
analysis in an array format, and the functional integration of these operations. In addition,
15 the present invention provides a procedure for the creation of material surfaces with desired
properties and for the fabrication of surface-mounted optical components.
